# or: Why responsive design works

Peter-Paul Koch

<http://quirksmode.org>

<http://twitter.com/ppk>

DevReach, 13 November 2017

I made  
something  
for you

# Viewport visualisation

<https://quirksmode.org/mobile/viewports/>

The screenshot shows a web browser window with the URL <https://quirksmode.org/mobile/viewports/>. The page title is "Viewports visualisation app ALPHA" and it notes "Requires DESKTOP browser - for now".

The main content area is divided into several sections:

- Top section:** "Viewports visualisation app ALPHA" with a note "Requires DESKTOP browser - for now". Below it, a box states "This layer has position: absolute".
- Yellow section:** "This layer has position: fixed". It contains text explaining the layout viewport and how it can move vertically. It also lists several actions: "Pan left (arrow left)", "Pan right (arrow right)", "Pinch-zoom in (⌘)", "Pinch-zoom out (⌘)", and "Double-tap to center (⌘)".
- Blue section:** "This layer has position: device-size". It contains text explaining the device-size viewport and how it can move horizontally. It also lists several actions: "Set to ideal layout viewport (f)", "Set to default layout viewport (d)", and "Show properties (p)".
- Right sidebar:** "Issues" section with a list of tasks:
  - Figure out how the hell this is ever going to work properly on a mobile device.
  - Fix ideal viewport bugs
  - Add page zoom
  - Add zoom reflow
  - Add desktop viewport (16/9)
  - Add very wide element sticking out of document. This requires the layout viewport to move horizontally.
  - Double-tap doesn't work when blue visual viewport element is outside the browser window. Caused by `elementFromPoint` being relative to the window and not the document. Solve this AND figure out if this is in fact a

At the bottom right, there is a section titled "Use the arrow keys to pan. Use z to zoom in, and x to zoom out. See the right column of the test site for the other functions." and another section titled "One thing you should know about: if the blue visual viewport element is off-screen, the double-tap (⌘) feature doesn't work." Below that, it says "docEl is shorthand for document.documentElement" and "Show properties (p)".

At the bottom, there are two columns of checkboxes for browser compatibility:

- Other browsers
- Chrome 61+
- My proposal
- Document to visual vp
- Document to layout vp

Pixels

# A pixel is not a pixel

- CSS pixels
- Device pixels

You already know what they are. You just don't realise it.

# CSS pixels

- CSS pixels are the ones we use in declarations such as `width: 190px` or `padding-left: 20px`
- They are an abstract construct
- Their size increases or decreases when the user zooms

Mobile is becoming increasingly important to web designers and developers because users expect a site to work on their phones. Simultaneously, the web is becoming increasingly important to the mobile world because it is the only way to deploy an application to any phone.

Nowadays most web conferences feature a mobile session, and most mobile conferences a web session. The obvious next step is Mobilism: a conference wholly dedicated to mobile web design and development.

Just like in 2011 we'll invite some of the best speakers from the web development and the mobile world to guide you through the confusing jumble of platforms, screen sizes, and browsers that is the mobile ecosystem.

# Device pixels

- Device pixels are the physical pixels on the device
- There's a fixed amount of them that depends on the device

# Device pixels

# Device pixels

# What kind of pixels?

In general, almost all pixels you use in your code will be CSS pixels.

The only exception is `screen.width`

... but `screen.width` is a serious problem that we'll study later

# Viewports

- The 34% is calculated relative to its container: the `<body>`.
- Every block-level element, including `<html>` and `<body>`, has an implicit width: 100%.
- So we get 34% of the `<body>` width of 100%.
- 100% of what? Of the `<html>` width, which is again 100%.

# Viewports

- The `<html>` element's width is calculated relative to the viewport.
- Also called the initial containing block.
- On desktop it's equal to the browser window width.
- On mobile it's more complicated.

# Viewports

- When you page-zoom in with Ctrl/Cmd +, you enlarge the CSS pixels
- and as a result fewer of them fit on the browser screen
- Thus the viewport becomes smaller

Mobile is becoming increasingly important to web designers and developers because users expect a site to work on their phones. Simultaneously, the web is becoming increasingly important to the mobile world because it is the only way to deploy an application to any phone.

Nowadays most web conferences feature a mobile session, and most mobile conferences a web session. The obvious next step is Mobilism: a conference wholly dedicated to mobile web design and development.

 BlackBerry

# Ideal layout viewport

- There are no wrong dimensions for the ideal layout viewport.
- They're what they need to be for the device they run on.
- (Admittedly, there are weird values. But they're not wrong.)

# Ideal layout viewport:

375px

320px

414px

# Viewports

So the desktop viewport has been split into two:

- layout viewport
- visual viewport

# Viewports

So the desktop viewport has been split into two:

- layout viewport
- visual viewport

Fun game: whenever you see “viewport” in a W3C spec, ask “Which viewport?”

# Viewports

So the desktop viewport has been split into two:

- layout viewport
- visual viewport

Fun game: whenever you see “viewport” in a W3C spec, ask “Which viewport?”

The spec *never* answers that question, because the viewports haven’t been officially specified.

# Viewports

So the desktop viewport has been split into two:

- layout viewport
- visual viewport

But there's a third construct:

- the document

# Visualisation

<https://quirksmode.org/mobile/viewports/>

The screenshot shows a web browser window with the URL <https://quirksmode.org/mobile/viewports/>. The page title is "Viewports visualisation app ALPHA" and it includes a note: "Requires DESKTOP browser - for now".

The page is divided into several sections:

- Top section:** "Viewports visualisation app ALPHA" with a note "Requires DESKTOP browser - for now".
- Yellow box:** "This layer has position: absolute".
- Yellow box:** "This layer has position: fixed".
- Main content area:** Contains text explaining the visual viewport and layout viewport, and a list of issues.
- Right sidebar:** Contains a list of issues and a "Show properties (p)" button.
- Bottom section:** "This layer has position: device-sized" with a "Show properties (p)" button.

The main content area includes the following text:

The like region is the visual viewport. As you can see, it can move across the layout viewport, pushing it down and up across the document as required.

The yellow region is the layout viewport. It constrains the rest site's CSS layout, and also serves as a window to look at the document. It can move anywhere, but in portrait, or normal size, it only moves vertically. By definition the document and the layout viewport have the same width; the document takes its value from the layout viewport, after all. Therefore panning the layout viewport left and right is impossible. It's only when the document contains elements that are way wider than the layout viewport that it's possible to pan the layout viewport, but that doesn't happen in this simple test.

By default the layout viewport is 300px wide; I set this as the default layout viewport for the desktop device this app emulates. You can switch to the ideal layout viewport, 300px (that's still BUGGY), and you'll see that interactions generally get simpler and zooming becomes less necessary. I chose the values 300 and 300 exactly because they never occur in the wild, so you've not tempted to evaluate this test up with an actual device.

There are links that trigger several actions, and also keyboard shortcuts for most of these actions. Try panning and zooming around to see what happens.

I have no clue yet how to get this thing working on actual mobile phones. It depends on you seeing both views at the same time.

The right sidebar contains the following issues:

- Figure out how the hell this is ever going to work properly on a mobile device.
- Fix ideal viewport bugs
- Add page zoom
- Add zoom reflow
- Add desktop viewport (16/9)
- Add very wide element sticking out of document. This requires the layout viewport to move horizontally.
- Double-tap doesn't work when blue visual viewport element is outside the browser window. Caused by `elementFromPoint` being relative to the window and not the document. Solve this AND figure out if this is in fact a

The bottom section contains the following text:

This layer has position: device-sized

Use the arrow keys to pan. Use z to zoom in, and x to zoom out. See the right column of the test site for the other functions.

One thing you should know about: if the blue visual viewport element is off-screen, the double-tap (t) feature doesn't work.

docEl is shorthand for `document.documentElement`

Show properties (p)

- Other browsers
- Chrome 61+
- My proposal
- Document to visual vp
- Document to layout vp

# Document and viewports

- The visual viewport moves inside the layout viewport.
- But the layout viewport may also move inside the document.
- Usually you don't notice, except when you use `position: fixed`

# position: fixed

“For a fixed positioned box, the containing block is established by the viewport.”

Great!

But WHICH viewport?

Browsers were first all over the place, but recently standardised on the layout viewport.

Note that this is not officially specified anywhere; W3C is still in state of denial.

# position

- position: absolute means the element is positioned relative to the document
- position: fixed means the element is positioned relative to the layout viewport
- ... and what about the visual viewport?

# position

- Ages ago I proposed position: device-fixed, that would position an element relative to the visual viewport, and also would take it out of the pinch zoom.
- So far only IE/Edge has implemented it.

3

Meta

viewport

# Meta viewport

- In order to create a responsive design we must set the layout viewport dimensions to the ideal layout viewport dimensions.
- How?

# Meta viewport

```
<meta name="viewport"  
  content="width=device-width">
```

# Meta viewport

```
<meta name="viewport"  
  content="width = device-width">
```

- By default, the layout viewport is between 768 and 1024 pixels wide.
- The meta viewport tag sets the width of the layout viewport to a value of your choice.
- You can use a pixel value (width=400)
- or you can use the device-width keyword to set it to the ideal layout viewport

# Meta viewport

```
<meta name="viewport"  
  content="width = device-width">
```

- I'm assuming this does not come as a surprise
- But ...
- did you know that the following does exactly the same?

# Meta viewport

```
<meta name="viewport"  
  content="initial-scale = 1">
```

- In theory, initial-scale gives the initial zoom level (where 1 = 100%)
- 100% of WHAT?
- Of the ideal layout viewport
- In practice, it also sets the layout viewport dimensions to the ideal layout viewport

# Meta viewport

```
<meta name="viewport"  
  content="initial-scale = 2">
```

- In theory, initial-scale = 2 tells the browser to zoom in to 200%.
- It does so, but many browsers set the layout viewport to half the ideal layout viewport.
- Why half? Because zooming to 200% means that only half as many CSS pixels fit the visual viewport

# Meta viewport

```
<meta name="viewport"  
  content="initial-scale = 1">
```

- And yes, this is weird.
- I wonder what Apple was smoking when it set these rules. I want some.

Let's mess  
things up

# Meta viewport

```
<meta name="viewport"  
  content="width = 400,initial-scale = 1">
```

- Now the browser gets conflicting orders.
- Set the layout viewport width to 400px.
- No, wait, set it to the ideal layout viewport width (and also set the zoom to 100%).
- Browsers react by taking the highest value

# Min-width viewport

```
<meta name="viewport"
```

```
content="width = 400,initial-scale = 1">
```

- “Set the layout viewport width to either 400px, or the ideal layout viewport width, whichever is larger”
- If the device orientation changes, this is recalculated.
- As a result, the layout viewport now has a minimum width of 400px.
- Is this useful? Dunno.

# Safari problem

```
<meta name="viewport"  
  content="width = device-width">
```

- Safari always takes the portrait width (320 on iPhone 5-, 768 on iPad).
- Sometimes this is what you want; at other times it isn't.
- How to solve this?

# Safari problem

```
<meta name="viewport"  
  content="initial-scale = 1">
```

- Now Safari does it right. In portrait mode it's the ideal portrait width; in landscape mode it's the ideal landscape width.
- All other browsers do the same.

# Safari problem

```
<meta name="viewport"  
content="width=device-width,initial-scale=1">
```

- Use both device-width and initial-scale.
- initial-scale works in Safari
- (device-width was needed for IE10, if you're still interested)
- and both work in all other browsers

# Perfect meta viewport

```
<meta name="viewport"  
  content="  
    width = device-width,  
    initial-scale = 1">
```

4

Media  
queries

# Media queries

```
@media all and (max-width: 600px) {  
  .sidebar {  
    float: none;  
  }  
}
```

# Media queries

- There are two important media queries:
- width (min-width and max-width)
- device-width (min-device-width and max-device-width)
- width is the one you want

Mobile is becoming increasingly important to web designers and developers because users expect a site to work on their phones. Simultaneously, the web is becoming increasingly important to the mobile world because it is the only way to deploy an application to any phone.

Nowadays most web conferences feature a mobile session, and most mobile conferences a web session. The obvious next step is Mobilism: a conference wholly dedicated to mobile web design and development.

Just like in 2011 we'll invite some of the best **speakers** from the web development and the mobile world to guide you through the confusing jumble of platforms, screen sizes, and browsers that is the mobile ecosystem.

Mobilism 2012, 10th and 11th of May, Amsterdam

## Featuring Remy Sharp and Jeremy Keith

[Buy tickets](#)

Mobile is becoming increasingly important to web designers and developers because users expect a site to work on their phones. Simultaneously, the web is becoming increasingly important to the mobile world because it is the only way to deploy an application to any device.

### width

These days most web conferences feature a mobile session, and most mobile conferences feature a web session. The obvious next step is Mobilism: a conference wholly dedicated to mobile design and development.

Like in 2011 we'll invite some of the best speakers from the web development and the mobile world to guide you through the confusing jumble of platforms, screen sizes, and devices that is the mobile ecosystem.

MOBILISM 2012, 10TH AND 11TH OF MAY, AMSTERDAM

*Featuring Remy Sharp and  
Jeremy Keith*

[Buy tickets](#)

Mobile is becoming increasingly important to web designers and developers because users expect a site to work on their phones. Simultaneously, the web is becoming increasingly important to the mobile world because it is the only way to deploy an application to any phone.

Nowadays most web conferences feature a mobile session, and most mobile conferences a web session. The obvious next step is Mobilism: a conference wholly dedicated to mobile web design and development.

 BlackBerry

# Responsive design

```
<meta name="viewport"  
content="width=device-width,initial-scale=1">
```

```
@media all and (max-width: 600px) {  
  
}
```

# Responsive design

- Set the layout viewport width to the ideal layout viewport width (or, rarely, another value)
- Use the width media query to figure out how wide the layout viewport is
- Adjust your CSS to the width you found
- That's how responsive design works. You already knew that, but now you understand **why** it works.

# Media queries

- Always use min- or max-width.
- Thus you define a breakpoint: “these styles are valid for all widths equal to or less/greater than X”
- Exact widths, such as 320, are going to misfire in a lot of browsers. (Even modern iPhones need different values.)

# 5 JavaScript properties

# Layout viewport dimensions

`document.documentElement.clientWidth`

`document.documentElement.clientHeight`

Works (almost) everywhere.

# Layout viewport offset

-document.

documentElement.

getBoundingClientRect().left/top

# JavaScript - visual viewport

`window.innerWidth`

`window.innerHeight`

Doesn't work in Android 2, Opera Mini, and UC 8.

Or in Chrome 61+.

# Visual viewport offset

`window.pageX/Yoffset`

Relative to the document.

# Visual viewport offset

`window.pageX/YOffset`

Relative to the document.

And what if you want the offset relative to the layout viewport? Not available.

But you can calculate it.

# Properties

<https://quirksmode.org/mobile/viewports/>

The screenshot shows a browser window titled "Viewports visualisation app ALPHA" with the URL <https://quirksmode.org/mobile/viewports/>. The page content is annotated with several boxes and arrows:

- A box at the top left contains the text: `-docEl.getBoundingClientRect().left/top` and `position: absolute`. An arrow points from this box to the `docEl.clientWidth` annotation.
- A yellow box in the middle contains the text: `docEl.clientWidth` and `fixed`. An arrow points from this box to the `docEl.clientHeight` annotation.
- A box in the middle left contains the text: `window.pageX/YOffset` or `window.scrollX/Y` and `unavailable`. An arrow points from this box to the `docEl.clientHeight` annotation.
- A box at the bottom left contains the text: `docEl.clientHeight` and `layout viewport, 900px`. An arrow points from this box to the `docEl.clientHeight` annotation.
- A box at the bottom center contains the text: `window.innerWidth` and `layout viewport, 900px`. An arrow points from this box to the `docEl.clientHeight` annotation.
- A box at the bottom right contains the text: `docEl.clientHeight` and `layout viewport, 900px`. An arrow points from this box to the `docEl.clientHeight` annotation.

On the right side of the page, there is a list of properties:

- `position: absolute`
- `position: device-fixed`

Below the list of properties, there is a section titled "Use the arrow keys to pan. Use z to zoom in, and x to zoom out. See the right column of the test site for the other functions."

One thing you should know about: if the blue visual viewport element is off-screen, the double-tap (t) feature doesn't work.

`docEl` is shorthand for `document.documentElement`

Show properties (p)

- Other browsers
- Chrome 61+
- My proposal
- Document to visual vp
- Document to layout viewport

# JavaScript properties

Confusing! Is there method to this madness?

Nope.

Back 10 years ago, mobile browser vendors needed new properties for new viewports.

The Browser Wars had left behind some IE- and Netscape-specific debris,

and mobile browser vendors just took it and shaped it.

# JavaScript properties

Meanwhile, W3C has *still* not specified any of this.

I mean, it's been only 10 years, so what's the rush?

Google, however, took action recently.

# Visual viewport

`window.visualViewport`

<code>width</code> and <code>height</code>	the width and height (surprise!)
<code>pageLeft</code> and <code>pageTop</code>	Offset relative to the document
<code>offsetLeft</code> and <code>offsetTop</code>	Offset relative to layout viewport
<code>scale</code>	Zoom level relative to layout viewport

# JavaScript properties

Sounds good, right?

# JavaScript properties

Sounds good, right?

Unfortunately, Google also decided that all old properties should refer to the layout viewport.

# JavaScript properties

Sounds good, right?

Unfortunately, Google also decided that all old properties should refer to the layout viewport.

`window.pageX/Yoffset`

- Visual viewport offset in all browsers
- Except for Chrome 61+, where it's the *layout* viewport offset

# JavaScript properties

Sounds good, right?

Unfortunately, Google also decided that all old properties should refer to the layout viewport.

`window.innerWidth/Height`

- Visual viewport dimensions
- Except for Chrome 61+, where it's the *layout* viewport dimensions

# JavaScript properties

But Google wouldn't be Google if it didn't make things needlessly complicated.

So here we are now ...

The theoretical solution is simple, but Google is not going to implement it

because Important Reasons

# Layout viewport

`window.layoutViewport`

<code>width</code> and <code>height</code>	the width and height (surprise!)
<code>pageLeft</code> and <code>pageTop</code>	Offset relative to the document
<del><code>offsetLeft</code> and <code>offsetTop</code></del>	<del>Offset relative to layout viewport</del>
<code>scale</code> ?	Zoom level relative to ... something?

# JavaScript properties

So we're stuck right now.

And there's something else ...

# screen.width

screen.width

screen.height

**UNRELIABLE!**

Some browsers define screen.width and screen.height as the dimensions of the ideal layout viewport

while others define them as the number of device pixels

# screen.width

Situation as of October 2016: not too bad, but some browsers have problems.

	iOS		iOS Web-View		And. 4	AWK Web-View	Chromium										Chromium WebView					UC 11	Black-Berry 10	Del-phin	Opera Mini		IE 11	Edge 14	Fire-fox 49
	9	10	9	10			LG	Cy	HTC	S34	MM	S44	Xia	Op	Th	Go	30	33	39	45	54				11	19			
<b>screen.width and screen.height</b> Dimensions of the ideal layout viewport.	portrait	physical	yes										yes	physical	yes	physical	yes	yes	layout	yes									

screen.width should return the dimensions of the ideal viewport. The older implementation returns the number of physical device pixels, but that's now seen as wrong.

**Physical**  
Gives the physical screen dimensions.

**Portrait**  
Always gives the portrait values even when in landscape.

**Layout**  
Gives the layout viewport dimensions, except that the toolbars are counted as well.

Note: Safari stuck in portrait mode.

# screen.width

Not reliable right now.

And there's something else ...

All analytics scripts that give you screen sizes?  
They're unreliable as well

because they use screen.width.

Check your logs: did you EVER see an iOS  
device in landscape mode?

You see?

# Depressed?

I hope you don't feel too depressed after this presentation.

Some things DO work well.

Still, having a minor depression is the proper reaction to these examples.

But you'll survive.

And the really important stuff DOES work.

# Thank you

I'll put these slides online

Questions?
